

# davos: a Python package “smuggler” for constructing lightweight reproducible notebooks

## Abstract

Reproducibility is a core requirement of modern scientific research. For computational research, reproducibility means that code should produce the same results, even when run on different systems. A standard approach to ensuring reproducibility entails packaging a project’s dependencies along with its primary code base. Existing solutions vary in how deeply these dependencies are specified, ranging from virtual environments (which specify all Python package versions), to containers (which also specify the operating system), to virtual machines (which also specify hardware layers of the system). Each of these existing solutions requires installing or setting up a system for running the desired code that must be packaged alongside the primary code base. Here we propose a lighter-weight solution than virtual environments: the **davos** library. When used in combination with a notebook-based Python project, the **davos** library provides a mechanism for specifying (and automatically installing) the correct package versions of the project’s dependencies. This enables researchers to share a complete reproducible environment using a single Jupyter notebook file.

## Required Metadata

### Current code version

Nr.	Code metadata description	Metadata value
C1	Current code version	v0.1.1
C2	Permanent link to code/repository used for this code version	<a href="https://github.com/ContextLab/davos/tree/v0.1.1">https://github.com/ContextLab/davos/tree/v0.1.1</a>
C3	Code Ocean compute capsule	
C4	Legal Code License	MIT
C5	Code versioning system used	git
C6	Software code languages, tools, and services used	Python, JavaScript, PyPI/pip, IPython, Jupyter, Ipykernel, PyZMQ. Additional tools used for tests: pytest, Selenium, Requests, mypy, GitHub Actions
C7	Compilation requirements, operating environments, and dependencies	Dependencies: Python $\geq 3.6$ , packaging, setuptools. Supported OSes: MacOS, Linux, Unix-like. Supported IPython environments: Jupyter notebooks, JupyterLab, Google Colaboratory, Binder, IDE-based notebook editors.
C8	Link to developer documentation/manual	<a href="https://github.com/ContextLab/davos#readme">https://github.com/ContextLab/davos#readme</a>
C9	Support email for questions	contextualdynamics@gmail.com

Table 1: Code metadata

## 1. Motivation and significance

Code sharing is a core component of the open science movement that has inspired the development of a full ecosystem of tools and packages. However, sharing code, in and of itself, does not guarantee that others will be able to *reproduce* the desired results. For example, research code often requires installing other software packages that extend the implementation language’s basic functionality. Within the Python community [1], external packages that are published in the most popular repositories [2, 3] are associated with version numbers and tags that enable users to guarantee that they are installing exactly the same code across different computing environments. Despite that it is *possible* to manually install the intended version numbers of every dependency of a Python script or package, doing so may cause conflicts within the

13 user’s computing environment that interfere with the functionality of *other*  
14 code.

15 To facilitate code sharing, the Python community has developed a broad  
16 set of approaches and tools (Fig. 1). At one extreme, simply publishing a set  
17 of Python scripts (.py files) may enable others to use or gain insights into  
18 the relevant work. Because Python is installed by default on most modern  
19 operating systems, for some projects this may be sufficient. Another popu-  
20 lar approach entails creating JSON files, called Jupyter notebooks [4], that  
21 comprise a mix of text, executable code, and embedded media. Notebooks  
22 may call or import external scripts or libraries in order to provide a more  
23 compact and readable experience for users. Each of these systems (Python  
24 scripts and notebooks) provides a convenient means of sharing code, with the  
25 caveat that they do not specify the computing environment in which the code  
26 is executed. Therefore the functionality of code shared using these systems  
27 cannot be guaranteed across different computing environments.

28 At another extreme, virtual machines [5, 6, 7] provide a hardware-level  
29 simulation of the desired system. Virtual machines are typically isolated  
30 from the user’s system, such that installing or running software on a virtual  
31 machine does not impact the user’s primary operating system or computing  
32 environment. Containers [e.g., 8, 9] provide a similar “isolated” experience.  
33 Although containerized environments do not specify hardware-level opera-  
34 tions, they are typically packaged with a complete operating system, in ad-  
35 dition to a complete copy of Python and any relevant package dependencies.  
36 Virtual environments [e.g., 10] also provide a computing environment that  
37 is largely separated from the user’s main environment. They incorporate  
38 a copy of Python and the target software’s dependencies, but virtual envi-  
39 ronments do not specify or reproduce an operating system for the runtime  
40 environment. Each of these systems (virtual machines, containers, and vir-  
41 tual environments) guarantees (to differing degrees– at the hardware level,  
42 operating system level, and Python environment level, respectively) that the  
43 relevant code will run similarly for different users. However, each of these  
44 systems also relies on additional software that can be resource intensive or  
45 burdensome to install or configure.

46 We designed **davos** to occupy a “sweet spot” between these extremes.  
47 **davos** is a notebook-installable package that adds functionality to the default  
48 notebook experience. Like standard Jupyter notebooks, **davos**-enhanced  
49 notebooks allows researchers to include text, executable code, and media  
50 within a single file. No further setup or installation is required, beyond what  
51 is needed to run standard Jupyter notebooks. And like virtual environments  
52 **davos** provides a convenient mechanism for fully specifying (and installing, as  
53 needed) a complete set of Python dependencies, including package versions.

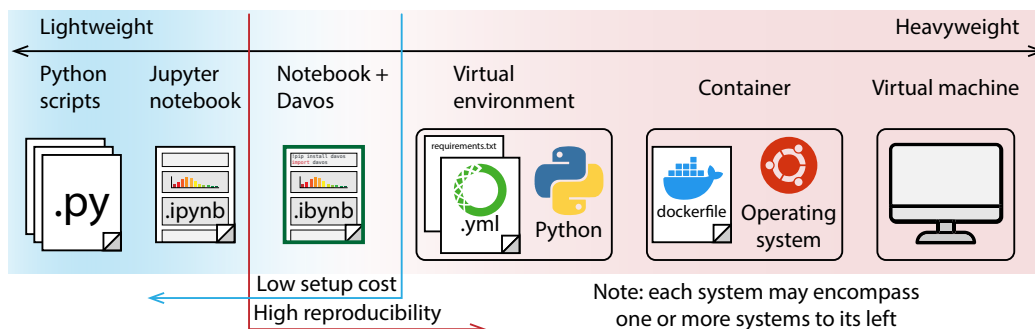

Figure 1: **Systems for sharing code within the Python ecosystem.** From left to right: plain-text **Python scripts** (`.py` files) provide the most basic “system” for sharing raw code. Scripts may reference external libraries, but those libraries are not automatically installed on other users’ systems, nor is any version checking performed by default. **Jupyter notebooks** (`.ipynb` files) comprise embedded text, executable code, and media (including rendered figures, code output, etc.). When the **davos** library is imported into a Jupyter notebook, the notebook’s functionality is extended to automatically install the required external libraries (at their correct versions, when specified). **Virtual environments** install an isolated copy of Python and all required dependencies. This typically requires defining a `requirements.txt` file that lists all dependencies (including version numbers) along with an environment (`.yml`) file that specifies how the virtual environment should be configured. **Containers** provide a means of defining an isolated environment that includes a complete operating system (independent of the user’s operating system), in addition to a virtual environment or other configurations needed to provide the necessary computing environment. Containers are typically defined using specification files (e.g., a plain-text `dockerfile`) that instruct the virtualization engine regarding how to build the virtual environment. **Virtual machines** provide a complete hardware-level simulation of the computing environment. In addition to simulating specific hardware, virtual machines (typically specified using binary images files) must also define operating system-level properties of the computing environment. Systems to the left of the blue vertical line entail sharing individual files, with no additional installation or configuration needed to run the target software. Systems to the right of the red vertical line provide high reproducibility by supporting precise control over dependencies and versioning. Notebooks enhanced using the **davos** library are easily shareable and require minimal setup costs, while also facilitating high reproducibility by enabling precise control over project dependencies.

## 54 2. Software description

### 55 2.1. Software architecture

56 The **davos** package is structured as two sub-packages: a set of “core”  
57 modules that implement...

### 58 2.2. Software functionalities

#### 59 2.2.1. The *smuggle* statement

60 Importing **davos** enables an additional Python keyword: “**smuggle**”. The  
61 **smuggle** statement can be used as a drop-in replacement for Python’s built-  
62 in **import** statement to load libraries, modules, and other objects into the  
63 current namespace. However, whereas **import** will fail if the requested pack-  
64 age is not installed locally, **smuggle** statements can handle missing packages  
65 on the fly. If a smuggled package does not exist in the local environment,  
66 **davos** will install it, expose its contents to Python’s **import** machinery, and  
67 load it into the namespace for immediate use.

#### 68 2.2.2. The *onion comment*

69 For greater control over the behavior of **smuggle** statements, **davos** de-  
70 fines an additional construct called the *onion comment*. An onion comment  
71 is a special type of inline comment that may be placed on a line containing a  
72 **smuggle** statement to customize how **davos** searches for the smuggled pack-  
73 age locally and, if necessary, how it should be installed. Onion comments  
74 follow a simple syntax based on the “type comment” syntax introduced in  
75 PEP 484 [10] and are designed to make managing packages via **davos** intu-  
76 itive and familiar. To construct an onion comment, simply provide the name  
77 of the installer program (e.g., **pip**) and the same arguments one would use  
78 to install the package as desired manually via the command line (see Fig. 2).

```
import davos

# if numpy is not installed locally, pip-install it and display verbose output
smuggle numpy as np      # pip: numpy --verbose

# pip-install pandas without using or writing to the package cache
smuggle pandas as pd     # pip: pandas --no-cache-dir

# install scipy from a relative local path, in editable mode
from scipy.stats smuggle ttest_ind      # pip: -e ../../pkgs/scipy
```

82	<b>3. Illustrative Examples</b>

## 83 4. Impact

84 Like virtual environments, containers, and virtual machines, the **davos** li-  
85 brary (when used in conjunction with Jupyter notebooks) provides a lightweight  
86 mechanism for sharing code and ensuring reproducibility across users and  
87 computing environments (Fig. 1). Further, **davos** enables users to fully  
88 specify (and install, as needed) any project dependencies within the same  
89 notebook. This provides a system whereby executable code (along with text  
90 and media) *and* code for setting up and configuring the project dependencies,  
91 may be combined within a single notebook file.

92 We designed **davos** for use in research applications. For example, in many  
93 settings **davos** may be used as a drop-in replacement for more-difficult-to-  
94 set-up virtual environments, containers, and/or virtual machines. For re-  
95 searchers, this lowers barriers to sharing code. By eliminating most of the  
96 setup costs of reconstructing the original researchers’ computing environ-  
97 ment, **davos** also lowers barriers to entry for members of the scientific com-  
98 munity and the public who seek to *benefit* from shared code.

99 Beyond research applications, **davos** is also useful in pedagogical settings.  
100 For example, in programming courses, instructors and students may import  
101 the **davos** library into their notebooks to provide a simple means of ensur-  
102 ing their code will run on others’ machines. When combined with online  
103 notebook-based platforms like Google Colaboratory, **davos** provides a con-  
104 venient way to manage dependencies within a notebook, without requiring  
105 any software (beyond a web browser) to be installed on the students’ or in-  
106 structors’ systems. For the same reasons, **davos** also provides an elegant  
107 means of sharing ready-to-run notebook-based demonstrations that install  
108 their dependencies automatically.

109 Our work also has several more subtle “advanced” use cases and poten-  
110 tial impacts. Whereas Python’s built-in **import** statement is agnostic to  
111 packages’ version numbers, **smuggle** statements (when combined with onion  
112 comments) are version-sensitive. This enables multiple versions of a single li-  
113 brary to be imported within the same notebook. This could be useful in cases  
114 where specific features were added or removed from a package across differ-  
115 ent versions, or in comparing the performance or functionality of particular  
116 features across different versions of the same package.

117 A second advanced use case is in providing a proof-of-concept of how one  
118 can add new “keywords” to the Python language by leveraging the error-  
119 handling mechanisms. This could lead to exciting new tools that, like **davos**,  
120 extend the Python language in useful ways. We note that our approach  
121 to adding the **smuggle** keyword to Python when **davos** is imported into a  
122 notebook-based environment also has the potential to be exploited for more  
123 nefarious purposes. For example, a malicious user could use a similar ap-  
124 proach (e.g., in a different library) to substantially change a notebook’s func-  
125 tionality by adding new *unexpected* keyword-like objects (e.g., based around  
126 common typos). This could lead to difficult-to-predict changes in a note-  
127 book’s behavior once the malicious library was imported. This highlights an  
128 important reason why security-conscious users would be well-served to only  
129 make use of libraries from trusted sources, or whose code is publicly available  
130 for review.

## 131 5. Conclusions

132 The **davos** library supports reproducible research by providing a novel  
133 lightweight system for sharing notebook-based code. But perhaps the most  
134 exciting uses of the **davos** library are those that we have *not* yet considered  
135 or imagined. We hope that the Python community will find **davos** to pro-  
136 vide a convenient means of managing project dependencies to facilitate code  
137 sharing. We also hope that some of the more advanced applications of our  
138 library might lead to new insights or discoveries.

## 139 Author Contributions

140 Conceptualization: PCF and JRM. Methodology: PCF and JRM. Imple-  
141 mentation: PCF. Validation: PCF. Testing: PCF and JRM. Writing: PCF  
142 and JRM.

## 143 Funding

144 Our work was supported in part by NSF grant number 2145172 to JRM.  
145 The content is solely the responsibility of the authors and does not necessarily  
146 represent the official views of our supporting organizations.

## 147 Declaration of Competing Interest

148 We wish to confirm that there are no known conflicts of interest associated  
149 with this publication and there has been no significant financial support for  
150 this work that could have influenced its outcome.

## 151 Acknowledgements

152 We acknowledge useful feedback and discussion from the students of  
153 JRM's *Storytelling with Data* course (Winter, 2022 offering) who used pre-  
154 liminary versions of our library in several assignments.
