

davos: a Python package “smuggler” for constructing lightweight reproducible notebooks

Paxton C. Fitzpatrick, Jeremy R. Manning*

*Department of Psychological and Brain Sciences

Abstract

Reproducibility is a core requirement of modern scientific research. For computational research, reproducibility means that code should produce the same results, even when run on different systems. A standard approach to ensuring reproducibility entails packaging a project’s dependencies along with its primary code base. Existing solutions vary in how deeply these dependencies are specified, ranging from virtual environments, to containers, to virtual machines. Each of these existing solutions requires installing or setting up a system for running the desired code that must be packaged alongside the primary code base. Here we propose a lighter-weight solution than virtual environments: the **davos** library. When used in combination with a notebook-based Python project, the **davos** library provides a mechanism for specifying (and automatically installing) the correct package versions of the project’s dependencies. The **davos** library also ensures that those versions are in use any time the notebook’s code is executed. This enables researchers to share a complete reproducible copy of their code within a single Jupyter notebook file.

Keywords: Reproducibility, Open science, Python, Jupyter Notebook, Google Colaboratory, Package management

Required Metadata

Current code version

Nr.	Code metadata description	Metadata value
C1	Current code version	v0.1.1
C2	Permanent link to code/repository used for this code version	https://github.com/ContextLab/davos/tree/v0.1.1
C3	Code Ocean compute capsule	
C4	Legal Code License	MIT
C5	Code versioning system used	git
C6	Software code languages, tools, and services used	Python, JavaScript, PyPI/pip, IPython, Jupyter, Ipykernel, PyZMQ. Additional tools used for tests: pytest, Selenium, Requests, mypy, GitHub Actions
C7	Compilation requirements, operating environments, and dependencies	Dependencies: Python ≥ 3.6 , packaging, setuptools. Supported OSes: MacOS, Linux, Unix-like. Supported IPython environments: Jupyter notebooks, JupyterLab, Google Colaboratory, Binder, IDE-based notebook editors.
C8	Link to developer documentation/manual	https://github.com/ContextLab/davos#readme
C9	Support email for questions	contextualdynamics@gmail.com

Table 1: Code metadata

1. Motivation and significance

The same computer code may not behave identically under different circumstances. For example, when code depends on external libraries, different versions of those libraries may function differently. Or when CPU or GPU instruction sets differ across machines, the same high-level code may be compiled into different machine instructions. Because executing identical code does not guarantee identical outcomes, code sharing in and of itself is often insufficient for enabling researchers to reproduce each other’s work.

Within the Python [1] community, external packages that are published in the most popular repositories [2, 3] are associated with version numbers and tags that enable users to guarantee that they are installing exactly the same

code across different computing environments. Despite that it is *possible* to manually install the intended version numbers of every dependency of a Python script or package, manually tracking down those dependencies can impose a substantial burden on the user.

Researchers, programmers, and others have developed a broad set of approaches and tools to facilitate code sharing and reproducible outcomes (Fig. 1). At one extreme, simply publishing a set of Python scripts (`.py` files) may enable others to use or gain insights into the relevant work. Because Python is installed by default on most modern operating systems, for some projects this may be sufficient. Another popular approach entails creating JSON files called Jupyter notebooks [4] that comprise a mix of text, executable code, and embedded media. Notebooks may call or import external scripts or libraries in order to provide a more compact and readable experience for users. Each of these systems (Python scripts and notebooks) provides a convenient means of sharing code, with the caveat that they do not specify the computing environment in which the code is executed. Therefore the functionality of code shared using these systems cannot be guaranteed across different computing environments.

At another extreme, virtual machines [5, 6, 7] provide a hardware-level simulation of the desired system. Virtual machines are typically isolated from the user’s system, such that installing or running software on a virtual machine does not impact the user’s primary operating system or computing environment. Containers [e.g., 8, 9] provide a similar “isolated” experience. Although containerized environments do not specify hardware-level operations, they are typically packaged with a complete operating system, in addition to a complete copy of Python and any relevant package dependencies. Virtual environments [e.g., 10] also provide a computing environment that is largely separated from the user’s main environment. They incorporate a copy of Python and the target software’s dependencies, but virtual environments do not specify or reproduce an operating system for the runtime environment. Each of these systems (virtual machines, containers, and virtual environments) guarantees (to differing degrees—at the hardware level, operating system level, and Python environment level, respectively) that the relevant code will run similarly for different users. However, each of these systems also relies on additional software that can be resource intensive or burdensome to install or configure.

We designed **davos** to occupy a “sweet spot” between these extremes. **davos** is a notebook-installable package that adds functionality to the default notebook experience. Like standard Jupyter notebooks, **davos**-enhanced notebooks allows researchers to include text, executable code, and media within a single file. No further setup or installation is required, beyond what

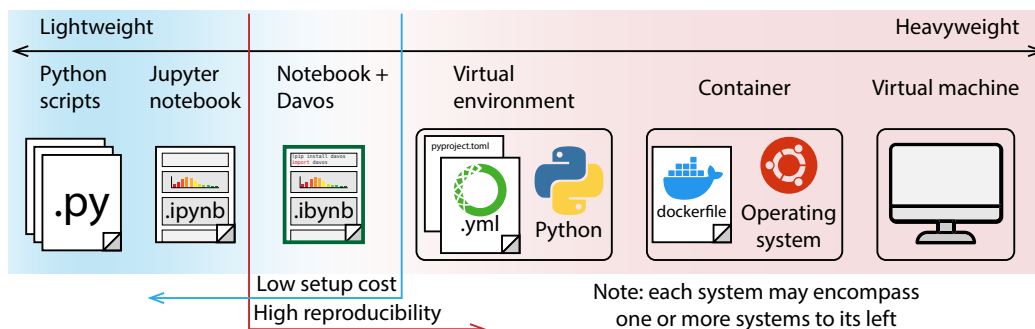

Figure 1: **Systems for sharing code within the Python ecosystem.** From left to right: plain-text **Python scripts** (`.py` files) provide the most basic “system” for sharing raw code. Scripts may reference external libraries, but those libraries must be manually installed on other users’ systems. Further, any checking needed to verify that the correct versions of those libraries were installed must also be performed manually. **Jupyter notebooks** (`.ipynb` files) comprise embedded text, executable code, and media (including rendered figures, code output, etc.). When the **davos** library is imported into a Jupyter notebook, the notebook’s functionality is extended to automatically install the required external libraries (at their correct versions, when specified). **Virtual environments** install an isolated copy of Python and all required dependencies. This typically requires defining a `requirements.txt` file or an environment (`.yml`) file that specifies all project dependencies (including version numbers of external libraries). **Containers** provide a means of defining an isolated environment that includes a complete operating system (independent of the user’s operating system), in addition to (optionally) specifying a virtual environment or other configurations needed to provide the necessary computing environment. Containers are typically defined using specification files (e.g., a plain-text **Dockerfile**) that instruct the virtualization engine regarding how to build the virtual environment. **Virtual machines** provide a complete hardware-level simulation of the computing environment. In addition to simulating specific hardware, virtual machines (typically specified using binary images files) must also define operating system-level properties of the computing environment. Systems to the left of the blue vertical line entail sharing individual files, with no additional installation or configuration needed to run the target code. Systems to the right of the red vertical line support precise control over dependencies and versioning. Notebooks enhanced using the **davos** library are easily shareable and require minimal setup costs, while also facilitating high reproducibility by enabling precise control over project dependencies.

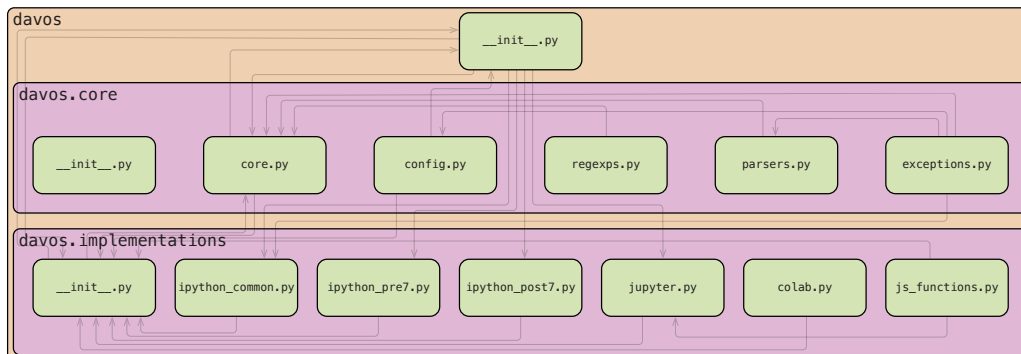

Figure 2: **Package structure.**

53 is needed to run standard Jupyter notebooks. And like virtual environments,
 54 **davos** provides a convenient mechanism for fully specifying (and installing, as
 55 needed) a complete set of Python dependencies, including package versions.

56 2. Software description

57 2.1. Software architecture

58 The **davos** package consists of two interdependent subpackages (see Fig. 2).
 59 The first, **davos.core**, comprises a set of modules that implement the bulk of
 60 the package’s core functionality, including pipelines for installing and validat-
 61 ing packages, custom parsers for the **smuggle** statement (see Section 2.2.1)
 62 and onion comment (see Section 2.2.2), and a runtime interface for config-
 63 uring **davos**’s behavior (see Section 2.2.3). However, certain critical aspects
 64 of this functionality require (often substantially) different implementation
 65 approaches depending on various properties of the notebook environment
 66 in which **davos** is used (e.g., whether the frontend is provided by Jupyter
 67 or Google Colaboratory, or which version of IPython [11] is used by the
 68 notebook kernel). To deal with this, environment-dependent parts of core
 69 features and behaviors are isolated and abstracted to “helper functions” in
 70 the **davos.implementations** subpackage. This second subpackage defines
 71 multiple, interchangeable versions of each helper function, organized into
 72 modules by the conditions that trigger their use. At runtime, **davos** detects
 73 various features in the notebook environment and selectively imports a single
 74 version of each helper function into the top-level **davos.implementations**
 75 namespace, allowing **davos.core** modules to access the correct implementa-
 76 tions for the current notebook environment in a single, consistent location.
 77 An additional benefit of this design pattern is that it allows maintainers or
 78 users to easily extend **davos** to support new, updated, or custom notebook

79 variants simply by creating a new `davos.implementations` module with any
80 necessary tweaks to existing helper functions.

81 *2.2. Software functionalities*

82 *2.2.1. The `smuggle` statement*

83 Importing `davos` in an IPython notebook enables an additional Python
84 keyword: “`smuggle`” (see Section 2.3 for details on how this works). The
85 `smuggle` statement can be used as a drop-in replacement for Python’s built-
86 in `import` statement to load libraries, modules, and other objects into the
87 current namespace. However, whereas `import` will fail if the requested pack-
88 age is not installed locally, `smuggle` statements can handle missing packages
89 on the fly. If a smuggled package does not exist in the local environment,
90 `davos` will install it automatically, expose its contents to Python’s `import`
91 machinery, and load it into the namespace for immediate use.

92 *2.2.2. The onion comment*

93 For greater control over the behavior of `smuggle` statements, `davos` de-
94 fines an additional construct called the “onion comment”. An onion comment
95 is a special type of inline comment that may be placed on a line containing a
96 `smuggle` statement to customize how `davos` searches for the smuggled pack-
97 age locally and, if necessary, downloads and installs it. Onion comments
98 follow a simple syntax based on the “type comment” syntax introduced in
99 PEP 484 [12], and are designed to make managing packages with `davos` intu-
100 itive and familiar. To construct an onion comment, simply provide the name
101 of the installer program (e.g., `pip`) and the same arguments one would use
102 to manually install the package as desired via the command line:

```
import davos

# if numpy is not installed locally, pip-install it and display verbose output
smuggle numpy as np      # pip: numpy --verbose

# pip-install pandas without using or writing to the package cache
smuggle pandas as pd     # pip: pandas --no-cache-dir

# install scipy from a relative local path, in editable mode
from scipy.stats smuggle ttest_ind      # pip: -e ../../pkgs/scipy
```

103

104 Onion comments are useful when smuggling a package whose distribution
105 name (i.e., the name used when installing it) is different from its top-level
106 module name (i.e., the name used when importing it):

```

smuggle dateutil      # pip: python-dateutil
from sklearn.decomposition smuggle PCA      # pip: scikit-learn

```

107

108 However, the most powerful use of the onion comment is making **smuggle**
 109 statements *version-sensitive*. If an onion comment includes a version spec-
 110 ifier [13], **davos** will ensure that the version of the package loaded into the
 111 notebook matches the specific version requested, or satisfies the given ver-
 112 sion constraints. If the smuggled package exists locally, **davos** will extract
 113 its version info from its metadata and compare it to the specifier provided. If
 114 the two are incompatible (or no local installation is found), **davos** will install
 115 and load a suitable version of the package instead:

```

# specifically use matplotlib v3.4.2, pip-installing it if needed
smuggle matplotlib.pyplot as plt      # pip: matplotlib==3.4.2

# use a version of seaborn no older than v0.9.1, but before v0.11
smuggle seaborn as sns      # pip: seaborn>=0.9.1,<0.11

```

116

117 Onion comments can similarly be used to smuggle specific VCS references
 118 (e.g., Git [14] branches, commits, tags, etc.):

```

# use quail as the package existed on GitHub at commit 6c847a4
smuggle quail      # pip: git+https://github.com/ContextLab/quail.git@6c847a4

```

119

120 **davos** processes onion comments internally before forwarding arguments to
 121 the installer program. In addition to preventing onion comments from being
 122 used as a vehicle for shell injection attacks, this allows **davos** take certain
 123 logical actions when particular arguments are passed. For example, the `-I/-`
 124 `--ignore-installed`, `-U/--upgrade`, and `--force-reinstall` flags will all
 125 cause **davos** to skip searching for a smuggled package locally before installing
 126 a new copy:

```

# install hypertools v0.7 without first checking for it locally
smuggle hypertools as hyp      # pip: hypertools==0.7 --ignore-installed

# always install the latest version of requests, including pre-releases
from requests smuggle Session      # pip: requests --upgrade --pre

```

127

128 Similarly, passing `--no-input` will temporarily enable **davos**'s non-interactive
 129 mode (see Section 2.2.2), and installing a smuggled package into `<dir>` with
 130 `--target <dir>` will cause `dir` to be prepended to the module search path
 131 (`sys.path`), if necessary, so the package can be imported

132 2.2.3. The *davos* config

133 The `davos` config object provides a simple, high-level interface that allows
134 users to view and set various options that affect `davos`'s behavior. After
135 importing `davos`, the config instance (a singleton) for the current session is
136 available as `davos.config`, and its various fields are accessible as attributes.
137 The config object exposes a mixture of writable and read-only fields. Writable
138 fields include:

- 139 • `.active`: Whether or not `davos` functionality (i.e., support for `smug-`
140 `gle` statements and onion comments) should be enabled for subsequent
141 code. Defaults to `True` when `davos` is first imported. See Section 2.3
142 for additional info.
- 143 • `.auto_rerun`: Controls behavior if `davos` is used to `smuggle` a new ver-
144 sion of a package that was previously imported and cannot be reloaded
145 (i.e., it contains C-extensions that dynamically generate code). If `True`
146 (default: `False`), `davos` will automatically restart the notebook kernel
147 and rerun all code up to (and including) the current `smuggle` state-
148 ment. Otherwise, `davos` will issue a warning, pause execution, and
149 prompt the user with buttons to either restart & rerun the notebook
150 or continue running with the imported package version. (Note: not
151 configurable in Google Colaboratory).
- 152 • `.confirm_install`: If `True` (default: `False`), `davos` will require user
153 confirmation (`[y]es/[n]o` input) before installing a smuggled package.
- 154 • `.noninteractive`: Setting to `True` (default: `False`) enables non-interactive
155 mode, in which all user input and confirmation is disabled. Note that
156 in non-interactive mode, the `confirm_install` option is set to `False`,
157 and if `auto_rerun` is `False`, `davos` will throw an error if a smuggled
158 package cannot be reloaded.
- 159 • `.pip_executable`: The path to the `pip` executable used to install
160 smuggled packages. Default is programmatically determined from the
161 Python environment and falls back to `sys.executable -m pip` if one
162 can't be found.
- 163 • `.suppress_stdout`: If `True` (default: `False`), suppress all unnecessary
164 output issued by both `davos` and the installer program. Useful when
165 smuggling packages that need to install many dependencies and/or gen-
166 erate extensive output. If the installer program throws an error, both
167 stdout and stderr will be shown with the traceback.

168 The top-level `davos` namespace additionally defines a handful of convenience
169 functions for setting and checking `davos`’s active/inactive state (`davos.activate()`;
170 `davos.deactivate()`; `davos.is_active()`) as well as the `davos.configure()`
171 function, which allows setting multiple config fields at once.

172 2.3. Implementation details

173 Functionally, importing `davos` appears to define “`smuggle`” as a Python
174 keyword, similar to “`import`”, “`def`”, or “`return`”. It also appears to cause
175 comments to be parsed, and their contents potentially able to affect code
176 behavior, which they normally are not. However, `davos` doesn’t actually
177 modify the rules of Python’s parser or lexical analyzer—in fact, modifying
178 the Python grammar isn’t possible at runtime, as doing so would require
179 rebuilding the interpreter. Instead, `davos` leverages the IPython notebook
180 backend to implement the `smuggle` statement and onion comment via a com-
181 bination of namespace injections and its own (far simpler) custom parser.

182 The `smuggle` keyword can be enabled and disabled at any time by “ac-
183 tivating” and “deactivating” `davos` (see Section 2.2.3, above). When `davos`
184 is first imported, it is activated automatically. Activating `davos` triggers
185 two actions: (1) the `smuggle()` function is injected into the IPython user
186 namespace, and (2) the `davos` parser is registered as a custom IPython input
187 transformer. IPython preprocesses all executed code as plain text before it is
188 sent to the Python parser, in order to handle special constructs like `%magic`
189 and `!shell` commands. `davos` hooks into this process to transform `smuggle`
190 statements into syntactically valid Python code. The `davos` parser uses a
191 complex regular expression [15] to match lines of code containing `smuggle`
192 statements (and, optionally, onion comments), extract relevant information
193 from their text, and replace them with equivalent calls to the `smuggle()`
194 function. For example, if a user runs a notebook cell containing

```
195 smuggle numpy as np      # pip: numpy>1.16,<=1.20 -vv
```

196 the code that is actually executed by the Python interpreter would be

```
197 smuggle(name="numpy", as_="np", installer="pip",  
        args_str="\"numpy>1.16,<=1.20 -vv\"",  
        installer_kwargs={'editable': False,  
                          'spec': 'numpy>1.16,<=1.20',  
                          'verbosity': 2})
```

198 Because the `smuggle()` function is defined in the notebook namespace, it is
199 also possible (though never necessary) to call it directly. Deactivating `davos`
200 will delete the name “`smuggle`” from the namespace, unless its value has

201 been overwritten and no longer refers to the `smuggle()` function. It will also
202 deregister the `davos` parser from the set of input transformers run when each
203 notebook cell is executed. While the overhead added by the `davos` parser is
204 de minimis, this may be useful, for example, when optimizing or precisely
205 profiling code.

206 3. Illustrative Examples

207 4. Impact

208 Like virtual environments, containers, and virtual machines, the `davos` li-
209 brary (when used in conjunction with Jupyter notebooks) provides a lightweight
210 mechanism for sharing code and ensuring reproducibility across users and
211 computing environments (Fig. 1). Further, `davos` enables users to fully
212 specify (and install, as needed) any project dependencies within the same
213 notebook. This provides a system whereby executable code (along with text
214 and media) *and* code for setting up and configuring the project dependencies,
215 may be combined within a single notebook file.

216 We designed `davos` for use in research applications. For example, in many
217 settings `davos` may be used as a drop-in replacement for more-difficult-to-
218 set-up virtual environments, containers, and/or virtual machines. For re-
219 searchers, this lowers barriers to sharing code. By eliminating most of the
220 setup costs of reconstructing the original researchers' computing environ-
221 ment, `davos` also lowers barriers to entry for members of the scientific com-
222 munity and the public who seek to *benefit* from shared code.

223 Beyond research applications, `davos` is also useful in pedagogical settings.
224 For example, in programming courses, instructors and students may import
225 the `davos` library into their notebooks to provide a simple means of ensur-
226 ing their code will run on others' machines. When combined with online
227 notebook-based platforms like Google Colaboratory, `davos` provides a con-
228 venient way to manage dependencies within a notebook, without requiring
229 any software (beyond a web browser) to be installed on the students' or in-
230 structors' systems. For the same reasons, `davos` also provides an elegant
231 means of sharing ready-to-run notebook-based demonstrations that install
232 their dependencies automatically.

233 Since its initial release, `davos` has found use in a variety of applications.
234 In addition to managing computing environments for multiple ongoing re-
235 search studies, `davos` is being used by both students and instructors in pro-
236 gramming and methods courses such as Storytelling with Data [16] (an open
237 course on data science, visualization, and communication) and Laboratory
238 in Psychological Science [17] (an open course on experimental and statistical

239 methods for psychology research) to simplify distributing lessons and sub-
240 mitting assignments, as well as in online demos such as `abstract2paper` [18]
241 (an example application of GPT-Neo [19, 20]) to share ready-to-run code
242 that installs dependencies automatically.

243 Our work also has several more subtle “advanced” use cases and poten-
244 tial impacts. Whereas Python’s built-in `import` statement is agnostic to
245 packages’ version numbers, `smuggle` statements (when combined with onion
246 comments) are version-sensitive. And because onion comments are parsed
247 at runtime, required package and their specified versions are installed in a
248 just-in-time manner. Thus, it is possible in most cases to `smuggle` a specific
249 package version or revision even if a different version has already been loaded.
250 This enables more complex uses that take advantage of multiple versions of
251 a package within a single interpreter session. This could be useful in cases
252 where specific features are added or removed from a package across differ-
253 ent versions, or in comparing the performance or functionality of particular
254 features across different versions of the same package.

255 A second advanced use case is in providing a proof-of-concept of how one
256 can add new “keyword-like” operators to the Python language by leverag-
257 ing notebooks’ error-handling mechanisms. This could lead to exciting new
258 tools that, like `davos`, extend the Python language in useful ways within
259 notebook-based environments. We note that our approach to adding the
260 `smuggle` keyword to Python when `davos` is imported into a notebook-based
261 environment also has the potential to be exploited for more nefarious pur-
262 poses. For example, a malicious user could use a similar approach (e.g.,
263 in a different library) to substantially change a notebook’s functionality by
264 adding new *unexpected* keyword-like objects (e.g., based around common ty-
265 pos). This could lead to difficult-to-predict changes in a notebook’s behavior
266 once the malicious library was imported. This highlights an important rea-
267 son why security-conscious users would be well-served to only make use of
268 libraries from trusted sources, or whose code is publicly available for review.

269 5. Conclusions

270 The `davos` library supports reproducible research by providing a novel
271 lightweight system for sharing notebook-based code. But perhaps the most
272 exciting uses of the `davos` library are those that we have *not* yet considered
273 or imagined. We hope that the Python community will find `davos` to pro-
274 vide a convenient means of managing project dependencies to facilitate code
275 sharing. We also hope that some of the more advanced applications of our
276 library might lead to new insights or discoveries.
