davos: The Python package smuggler

Paxton C. Fitzpatrick, Jeremy R. Manning*

Department of Psychological and Brain Sciences Dartmouth College, Hanover, NH 03755

Abstract

Reproducible code plays many important roles in modern scientific research: it enables scientists to collaborate on projects, replicate and extend prior work, and teach students new concepts and techniques via hands-on, interactive tutorials. However, existing tools that facilitate creating, sharing, and running reproducible code are often highly complex and resource-intensive, creating barriers to both contributing to and benefitting from open science resources. Here, we introduce davos, a Python package that allows users to create and share reproducible workflows

davos is also more effective at ____ than typical tools,

Keywords: Reproducibility, Open science, Python, Jupyter Notebook, Google Colaboratory, Package management

Table 1: Code metadata

1. Motivation and significance

- Modern scientific research often entails writing software code for a wide
- ³ variety of purposes throughout the scientific process. Researchers across dis-
- 4 ciplines may design and implement complex experiments; collect, store, and
- 5 analyze large datasets; create visualizations for presentations and publica-
- 6 tions; and share their findings and techniques with peers, students, and the
- broader public through tutorials, demos, workshops, and classes. However,
- one requirement common to virtually all forms of research-related code is
- 9 that its behavior and outputs remain consistent and predictable, no matter
- when, where, or by whom it is run. This stability can be crucial to ensuring,
- for example, that data are collected under the same conditions (e.g., across

recordings, trials, or subjects) over multiple months or years, and that they can be accessed, processed, and analyzed consistently by a research team that may be spread across multiple institutions or countries. Additionally, modern open science practices encourage publicly sharing research code and data so that others may explore, reproduce, learn from, and build upon existing work. Much of the benefit afforded by freely available research code depends on users' ability to execute it and achieve the same result as its original author.

Python [1] has become one of the most widely used and fastest-growing scientific programming languages, in part by combining an accessible, highlevel syntax with a rich ecosystem of powerful third-party tools that facilitate rapid development and collaboration [2]. The Python ecosystem offers an extensive data science toolkit with platforms for interactive programming (e.g., Project Jupyter [3], Google Colaboratory), community-maintained libraries for data manipulation (e.g., NumPy [4], SciPy [5], Pandas [6]) and visualization (e.g., Matplotlib [7], seaborn [8]), frameworks for training complex machine learning models (e.g., scikit-learn [9], TensorFlow [10], Hugging Face [11]), and myriad other resources. However, this heavy emphasis on third-party libraries also presents a challenge to writing and sharing stable, reproducible scientific Python code: different versions of the same library may behave differently, adopt changes in syntax, expose different functions and interfaces, add or drop support for specific hardware or software, write (or expect to read) files in different formats, fix (or introduce) bugs, and While these issues exist to some extent in any software language or ecosystem, they have a particular impact on the Python community due to its unusually rapid growth relative to other languages. Ensuring Python code behaves consistently over time and across users therefore typically requires ensuring it is always run with the same specific set of versions for each third-party package used.

One common approach to solving this problem is to create containerized or virtualized Python environments (e.g., using Docker [12], Singularity [13], or conda [14]) tailored to individual applications. A researcher may build such an environment around a specific experiment or analysis pipeline, and exclusively run their code from inside it, "entering" and "exiting" the environment before and after each time they do so. They can also share their custom environment alongside their code as a configuration file that explicitly lists required package versions, enabling others to build identical copies for themselves.

While often effective, this approach bears two notable drawbacks. First, it can add substantially to the technical knowledge, computing resources, and initial setup needed to run or share the actual code of interest. For

example, sharing an analysis or tutorial that relies on a particular Docker image to run properly would, of course, necessitate writing and distributing extra configuration files and setup instructions. While this may seem like merely a minor inconvenience to a researcher seasoned

But far more significantly, it would also require both the original author and anyone else who may want to run their code to first be able to install and be able to use additional software that is likely more complex and resource-intensive than the actual code it facilitates running. These added prerequisites clash with the simplicity and accessibility that have contributed to Python's popularity, and can create significant barriers to both contributing to and taking advantage of open science resources.

Second, while many existing tools allow users to populate a Python environment with a fixed set of packages and package versions (e.g., from a requirements.txt, pyproject.toml, environment.yml, Pipfile, Dockerfile RUN instruction, etc.), few, if any, enforce that these specified requirements remain satisfied after they are initially installed. The ability to modify an environment after its creation is useful in many cases (e.g., to install additional software, as needed); however, it also makes it easy to inadvertently alter existing packages, potentially leading to subtle issues with code that relies on them. For instance, suppose a researcher has implemented a series of analyses using version 1.0 of "Package X," and decides to perform an additional analysis that requires installing "Package Y." If Package Y depends on version 0.9 of Package X, then Package X will be downgraded to accommodate this new requirement, potentially altering or breaking previous analyses for both the researcher and anyone with whom they may later share their code. Further, if some analyses require Package Y while others rely on a feature of Package X not implemented until version 1.0, it's unclear which version the researcher should install in their environment.

The davos package provides a novel, Python-native framework for creating, sharing, and running reproducible workflows that was designed to address each of these issues.

Simply importing davos in a Jupyter notebook

davos was designed specifically for use in Jupyter notebook (formerly called IPython notebook [15]) environments, and supports Jupyter notebooks [3], JupyterLab [16], Google Colaboratory, Binder [17], and IDE-based notebook editors.

In simple use cases, davos can be used in lieu of more complicated environment management software, entirely eliminating the need for additional configuration files, pre-execution setup, and . For more complex

davos can be used on its own, in lieu of

2. Software description

94 2.1. Software architecture

The davos package is structured as two subpackages: a set of "core" modules that implement

97 2.2. Software functionalities

98 2.2.1. The smuggle statement

Importing davos enables an additional Python keyword: "smuggle". The smuggle statement can be used as a drop-in replacement for Python's built-in import statement to load libraries, modules, and other objects into the current namespace. However, whereas import will fail if the requested package is not installed locally, smuggle statements can handle missing packages on the fly. If a smuggled package does not exist in the local environment, davos will install it, expose its contents to Python's import machinery, and load it into the namespace for immediate use.

2.2.2. The onion comment

For greater control over the behavior of smuggle statements, davos defines an additional construct called the *onion comment*. An onion comment is a special type of inline comment that may be placed on a line containing a smuggle statement to customize how davos searches for the smuggled package locally and, if necessary, how it should be installed. Onion comments follow a simple syntax based on the "type comment" syntax introduced in PEP 484 [18], and are designed to make controlling installation via davos intuitive and familiar. To construct an onion comment, simply provide the name of the installer program (e.g., pip) and the same arguments one would use to install the package as desired manually via the command line (see Fig. 1).

```
import davos

# if numpy is not installed locally, pip-install it and display verbose output
smuggle numpy as np  # pip: numpy --verbose

# pip-install pandas without using or writing to the package cache
smuggle pandas as pd  # pip: pandas --no-cache-dir

# install scipy from a relative local path, in editable mode
from scipy.stats smuggle ttest_ind  # pip: -e ../../pkgs/scipy
```

```

3. Illustrative Examples

123 4. Impact

Despite the short time since its conception and initial release, davos has 124 already found use in a variety of applications. In addition to managing data 125 analysis environments for multiple ongoing research studies, davos is being 126 used by both students and instructors in programming courses such as Sto-127 rytelling with Data [19] (an open course on data science, visualization, and 128 communication) to simplify distributing lessons and submitting assignments, as well as in online demos such as abstract2paper [20] (an example appli-130 cation of GPT-Neo) to share ready-to-run code that installs dependencies 131 automatically. 132
